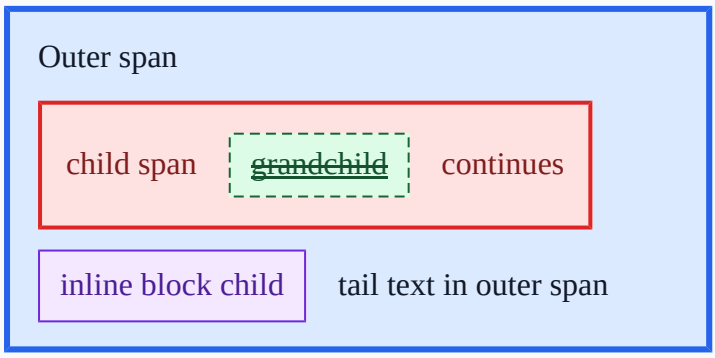
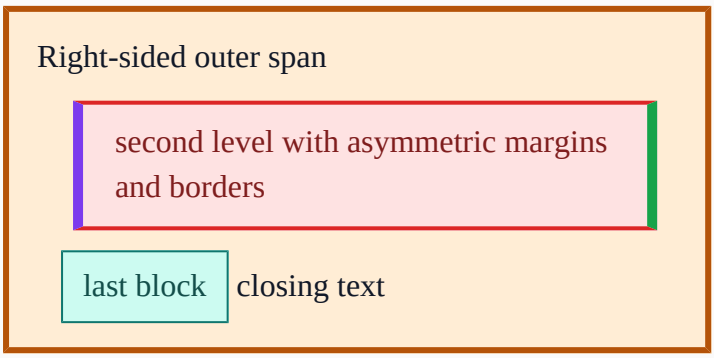
Case 1: parent span with nested children and asymmetric spacing



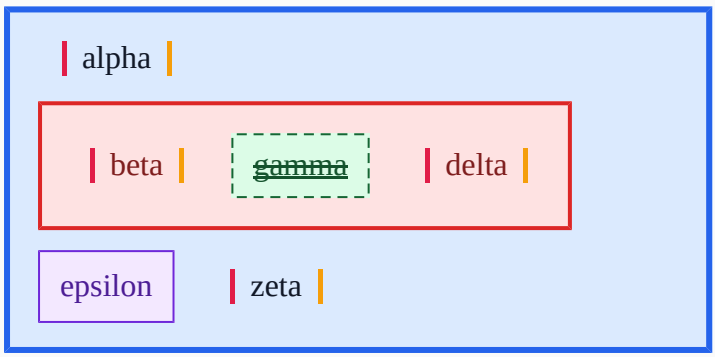
This paragraph text is visually next to the inline-block container and demonstrates how nested span styles are treated when no float is involved. Margins, padding and borders are still applied separately on each nested level.

Case 2: right-aligned parent with nested asymmetric borders and padding



A second paragraph demonstrates the same nested span behavior without any floating. The result should stay close to browser rendering for a normal inline formatting context while preserving manual adjustments for margin and border differences.

Case 3: multiple nesting levels with mixed inline text and span children



This third example combines multiple nesting levels and several properties that are resolved separately for the parent and child spans. It is useful to compare how margins, paddings, borders, and underline/line-through decoration

behave in a plain non-floating layout.
