Case 1: parent float + nested children with margins / borders / paddings

Outer span child span ~~grandchild~~ continues float child This paragraph text is intentionally long so it wraps around the floating block. It should remain on the left side of the container while the nested spans inside the floated box keep their own border, padding and margin values.

tail text in outer span

Case 2: right-floating parent with a nested block-like child and a last-child float

A second paragraph demonstrates the same behavior on the right side. The visual result should stay close to browser rendering even though nested span properties are resolved with compatibility workarounds instead of full CSS nesting support.

second level with asymmetric margins and borders

Right-sided outer span

closing text

last float

Case 3: mixed inline text segments and nested spans at multiple levels

alpha beta ~~gamma~~ delta epsilon zeta This third example combines multiple nesting levels and several properties that behave differently depending on whether they are applied to the parent span or to each child. Text decoration is expected to be split by independent text chunks rather than rendered as a single line across the whole span.
